

JVMCSP

Approaching Billions of Processes on a Single-Core JVM

Cabel Shrestha & Matt B. Pedersen

UNLV

HOWARD R. HUGHES

College of

ENGINEERING

Last Time ... (CPA 2014)

Towards
~~Hundreds of thousands~~
~~Tens of thousands of~~
Processes on the JVM

Matt Pedersen & Andreas Stefix
Department of Computer Science
University of Nevada Las Vegas

UNLV

We presented

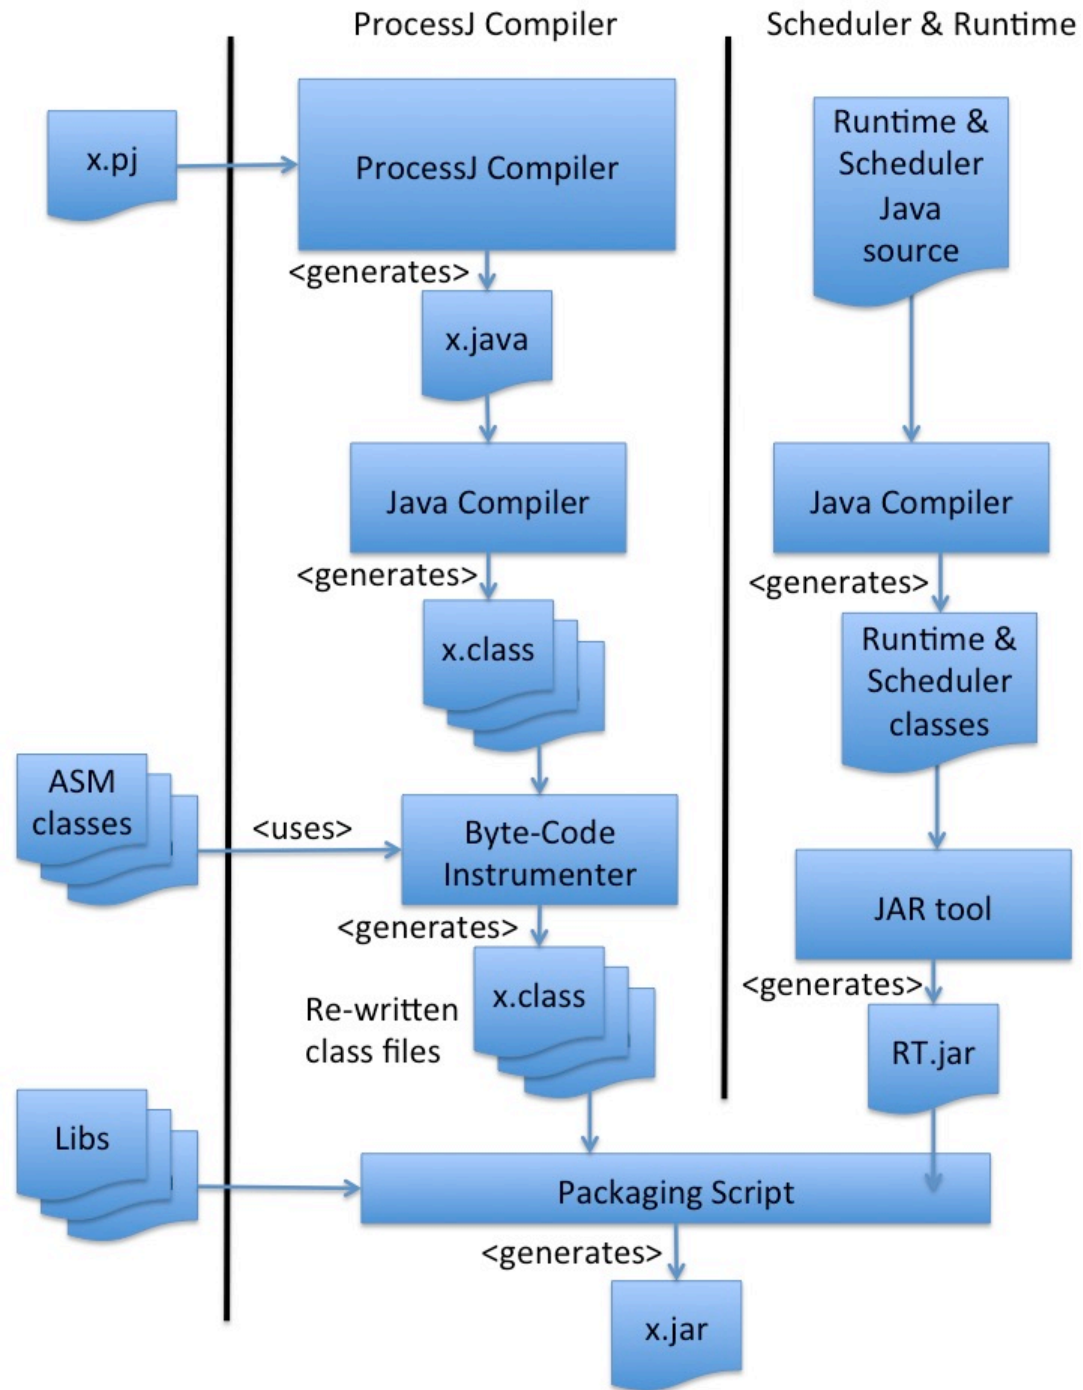

- ProcessJ
(Process-Oriented Language)
- Handcrafted JVM runtime:
LiteProc (proof of concept)
- ~ 95,000,000 concurrent
processes

This Time ... (CPA 2016)

- An implemented code generator in ProcessJ
- New improved runtime
 - Faster
 - Handles more processes

From ProcessJ to Java Bytecode

- ProcessJ compiler produces Java source code.
- Compiled with Javac.
- Instrumented with ASM byte code manipulation tool.
- Jar'd together with runtime

Runtime (Scheduler)

➤ User-level scheduler

➤ Cooperative, non-preemptive.

```
Queue<Process> processQueue;  
...  
// enqueue one or more processes to run  
while (!processQueue.isEmpty()) {  
    Process p = processQueue.dequeue();  
    if (p.ready())  
        p.run();  
    if (!p.terminated())  
        processQueue.enqueue(p);  
}
```

Essential Questions

- How does a procedure yield?
- When does a procedure yield and who decides?
- How is a procedure restarted after yielding?
- How is local state maintained?
- How are nested procedure calls handled when the innermost procedure yields?

How does a procedure yield? When does it yield and who decides?

CPA 2014 version

- Yields by calling return
- Procedures voluntarily give up the CPU at synchronization points

JVMCSP

- Yields by calling return
- Procedures voluntarily give up the CPU at synchronization points

Reads, writes, barrier syncs, alts,
timer operations: procedure returns
to scheduler (Bytecode: return)

How is a procedure restarted?

CPA 2014

- Procedure is simply recalled by scheduler

JVMCSP

- Procedure is simply recalled by scheduler

- How do we ensure that local state survives?
- How do we avoid restart from the top of the code?

Preservation of Local State

CPA 2014

- An activation record structure was used to store locals.
- Each procedure is a class with an activation stack.

JVMCSP

- All locals and fields have been converted to fields.
- Each procedure is a class.

Correct Resumption

CPA 2014

- Insert an empty switch statement at the top of the code to hold jumps.
- Instrument (by hand in decompiled bytecode) jumps to the correct resume points.

JVMCSP

- Insert an empty switch statement at the top of the generated code (source) to hold jumps.
- Instrument (by using ASM) jumps to the correct resume points.

A resume point counter (called `runLabel`) is kept for each process to remember where to continue.

Correct Resumption (Abstract)

➤ Each synchronization point is a yield point:

L1:

```
.. synchronize (read, sync etc)
if (succeeded)
    yield(L2); // return to L2 when resumed
else
    yield(L1); // return to L1 when resumed
```

L2:

Correct Resumption (Generated Code)

➤ Each synchronization point is a yield point:

```
label(1);  
.. synchronize (read, sync etc)  
if (succeeded)  
    yield(2);  
else  
    yield(1);  
label(2);
```

`yield(i)` will set the runlabel for the process object to `i`.

Correct Resumption (ASM Instrumentation)

```
label(1);  
.. synchronize  
if (succeeded)  
    yield(2);  
else  
    yield(1);  
label(2);
```

```
61: aload_0  
62: iconst_1  
63: invokevirtual label/(I)V  
66: ...  
...  
61: nop  
62: nop  
63: nop  
64: nop  
65: nop  
66: ...  
...
```

Dummy invocations
are removed.

Correct Resumption (ASM Instrumentation)

- This address (61) is associated with runlabel 1.
- Upon resumption, the code must jump to address 61 if the runlabel is 1.

```
61: nop  
62: nop  
63: nop  
64: nop  
65: nop  
66: ...  
...
```

Correct Resumption (Generated Code)

Generated Java Code

(top of the code)

```
switch (runlabel) {  
  case 0: resume(0);  
    break;  
  case 1: resume(1);  
    break;  
  ...  
  case k: resume(k);  
    break;  
}
```

Equivalent Java Bytecode

```
0: aload 0  
1: getfield runLabel  
4: tableswitch // 0 to 2  
  0: 32  
  1: 35  
  2: 43  
  default: 48  
32: goto 48  
35: aload 0  
36: iconst 1  
37: invokevirtual resume/(I)V  
40: goto 48  
...
```

Correct Resumption (ASM Instrumentation)

```
0: aload 0
1: getfield runLabel
4: tableswitch // 0 to 2
   0: 32
   1: 35
   2: 43
   default: 48
32: goto 48
35: aload 0
36: iconst 1
37: invokevirtual resume/(I)V
40: goto 48
...
```

Runlabel 1

```
0: aload 0
1: getfield runLabel
4: tableswitch // 0 to 2
   0: 32
   1: 35
   2: 43
   default: 48
32: goto 48
35: nop
36: nop
37: goto 61
40: goto 48
...
```

@ of runlabel 1

Placeholder code replaced by `nop` instructions and `gotos` adjusted to the correct label addresses

Correct Suspension

`yield(2);`

Becomes

```
78: aload_0
79: iconst_2
80: invokevirtual yield/(I)V
83: goto 100
...

100: return
```

Shared return point

`yield(2)` sets the `runLabel` field.

From ProcessJ to Java

```
proc void foo( $tp_1 pn_1, \dots, tp_n pn_n$ ) {  
  ...  
   $lt_1 ln_1;$   
  ...  
   $lt_m ln_m;$   
  ... statements ...  
}
```

The diagram illustrates the mapping of ProcessJ code to Java components. A red arrow labeled "Locals" points from the parameter list to the local variable declarations. A red arrow labeled "Parameters" points from the parameter list to the function signature. A red arrow labeled "Code" points from the function body to the code block.

From ProcessJ to Java

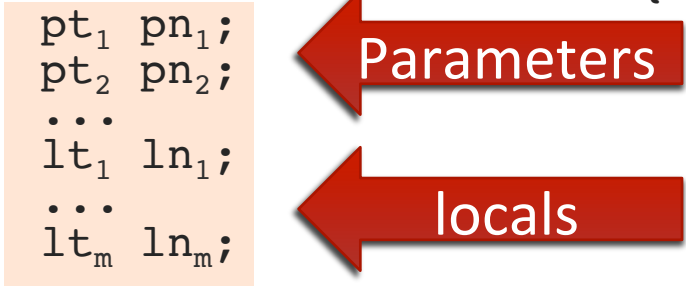

New class

```
public class A {  
    public static class foo  
        extends PJProcess {  
  
  
    }  
}
```

Process foo lives in a file called A.pj

From ProcessJ to Java

```
public class A {  
    public static class foo  
        extends PJProcess {  
        pt1 pn1;  
        pt2 pn2;  
        ...  
        lt1 ln1;  
        ...  
        ltm lnm;  
    }  
}
```

Locals and Parameters are turned into fields

From ProcessJ to Java

```
public class A {  
    public static class foo  
        extends PJProcess {  
        pt1 pn1;  
        pt2 pn2;  
        ...  
        lt1 ln1;  
        ...  
        ltm lnm;  
    }  
}
```

```
public foo(pt1 pn1, ...,  
           tpn pnn) {  
    this.pn1 = pn1;  
    ...  
    this.pnn = pnn;  
}
```

Constructor

Constructors set the parameters

From ProcessJ to Java

Run method 

```
public class A {
    public static class foo
        extends PJProcess {
        pt1 pn1;
        pt2 pn2;
        ...
        lt1 ln1;
        ...
        ltm lnm;

        public foo(pt1 pn1, ...,
                  tpn pnn) {
            this.pn1 = pn1;
            ...
            this.pnn = pnn;
        }
    }
}
```

```
public void run() {
}
}
```

run method is called by the scheduler

From ProcessJ to Java

```
public class A {  
    public static class foo  
        extends PJProcess {  
        pt1 pn1;  
        pt2 pn2;  
        ...  
        lt1 ln1;  
        ...  
        ltm lnm;  
  
        public foo(pt1 pn1, ...,  
                  tpn pnn) {  
            this.pn1 = pn1;  
            ...  
            this.pnn = pnn;  
        }  
    }  
}
```

Jump switch 

```
public void run() {  
    switch (runlabel) {  
        case 0: resume(0);  
                break;  
        case 1: resume(1);  
                break;  
        ...  
        case k: resume(k);  
                break;  
    }  
}
```

resume () calls replaced by jumps to label ()s

From ProcessJ to Java

```
public class A {  
    public static class foo  
        extends PJProcess {  
        pt1 pn1;  
        pt2 pn2;  
        ...  
        lt1 ln1;  
        ...  
        ltm lnm;  
  
        public foo(pt1 pn1, ...,  
                  tpn pnn) {  
            this.pn1 = pn1;  
            ...  
            this.pnn = pnn;  
        }  
    }  
}
```

```
public void run() {  
    switch (runlabel) {  
        case 0: resume(0);  
                break;  
        case 1: resume(1);  
                break;  
        ...  
        case k: resume(k);  
                break;  
    }  
    ... Statements  
}
```

Code is translated ProcessJ + generated primitives

Yielding in Nested Calls

CPA 2014

- Maintain a complex activation stack.
 - Constant creation and destruction of activation records.
 - Resumptions started from the outermost procedure and worked its way in

JVMCSP

- Calls of procedures that may yield

$f(x)$ becomes

```
par {  
     $f(x)$   
}
```

JVMCSP Runtime Components

- `PJProcess` represents a process.
- `PJPar` represents a par block.
- `PJChannel` represents a channel.
 - `PJOne2OneChannel`, `PJOne2ManyChannel`,
`PJMany2OneChannel`, `PJMany2ManyChannel`
- `PJBarrier` represents a barrier.
- `PJTimer` represents a timer.
- `PJAlt` represents an alt.

Par Blocks

```
par {  
    f(8);  
    g(9);  
}
```

becomes

```
final PJPar par1 = new PJPar(2, this);  
(new A.f(8) {  
    public void finalize() {  
        par1.decrement();  
    }  
}).schedule();  
(new A.g(8) {  
    public void finalize() {  
        par1.decrement();  
    }  
}).schedule();  
setNotReady();  
yield(1);  
label(1);
```

Par Blocks

Create new PJPar object
with 2 processes

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Par Blocks

Instantiate an f process

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Par Blocks

Decrement process
count of par when done

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Par Blocks

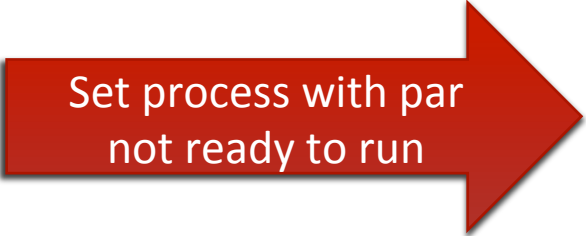

Schedule the process

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Par Blocks

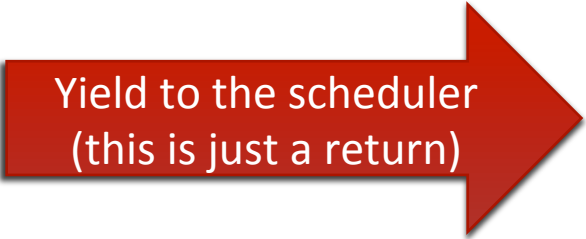

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Set process with par
not ready to run

Par Blocks

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

Yield to the scheduler
(this is just a return)

Par Blocks

```
final PJPar par1 = new PJPar(2, this);
(new A.f(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
(new A.g(8) {
    public void finalize() {
        par1.decrement();
    }
}).schedule();
setNotReady();
yield(1);
label(1);
```

When ready again
continue here

Channel Read

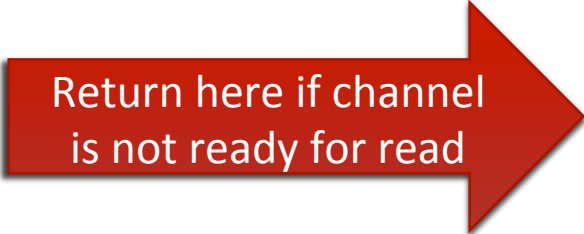

```
x = in.read();
```

Becomes

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

Channel Read

Return here if channel
is not ready for read

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

Channel Read

If the channel is
ready (data present)

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

Channel Read

Read

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

Channel Read

Yield and return
at label 3

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

Channel Read

```
...  
label(2);  
if (in.isReadyToRead(this)) {  
    x = in.read();  
    yield(3);  
} else {  
    setNotReady();  
    in.addReader(this);  
    yield(2);  
}  
label(3);
```

If no, set this process
not read to run

Channel Read

```
...
label(2);
if (in.isReadyToRead(this)) {
    x = in.read();
    yield(3);
} else {
    setNotReady();
    in.addReader(this);
    yield(2);
}
label(3);
```

Add the reader to the
channel

Channel Read

```
...
label(2);
if (in.isReadyToRead(this)) {
    x = in.read();
    yield(3);
} else {
    setNotReady();
    in.addReader(this);
    yield(2);
}
label(3);
```

Yield and return
at label 2 next time

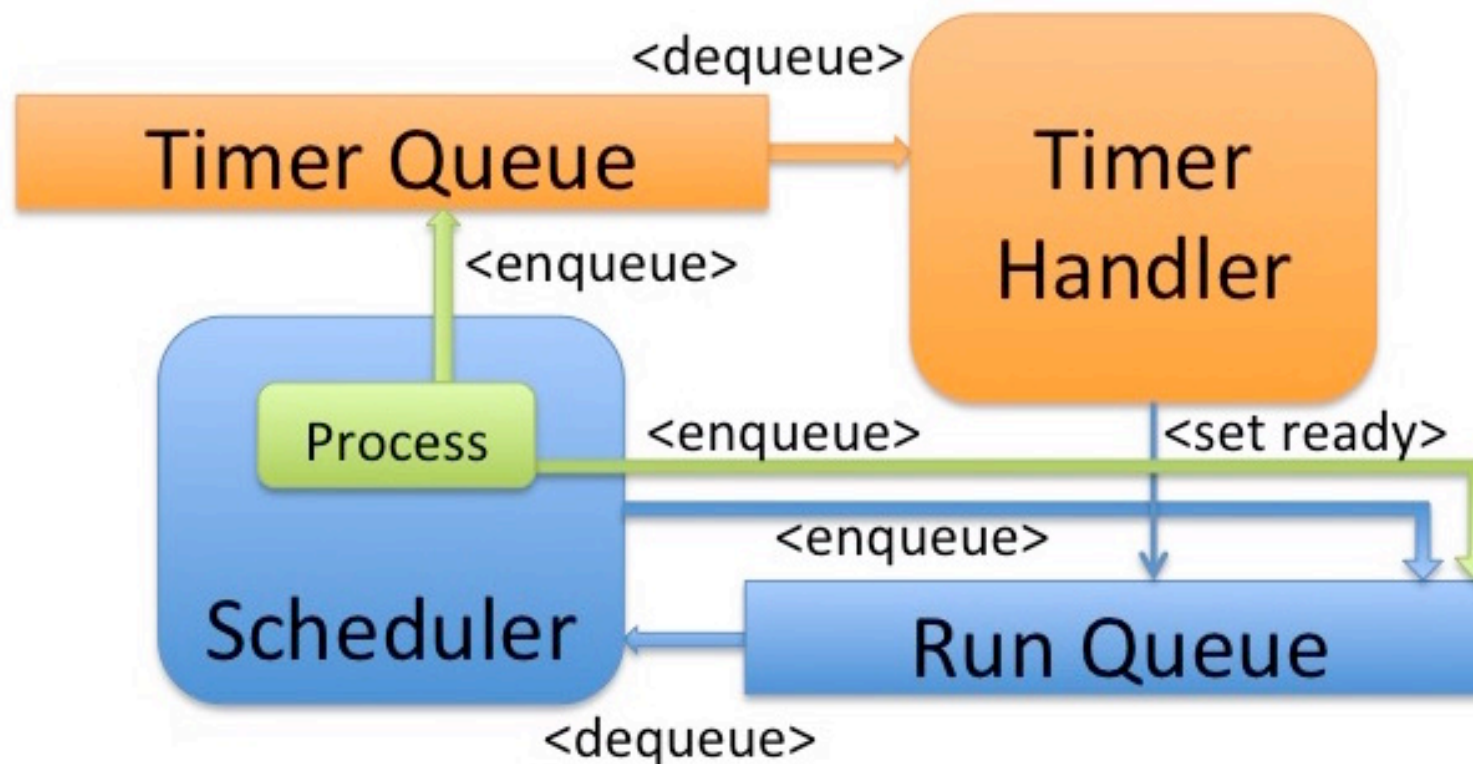

Other Channel Operations

- Channel writes are similar to reads.
- Channels with shared ends must be claimed.
 - Functionality to claim and unclaim is included in PJ...2... channel classes.

Timers and the Timer Queue

- Timers are handled by a TimerQueue and a TimerHandler.
 - The TimerQueue is a delay-queue.
 - Timeout calls cause insertions into TimerQueue
- TimerHandler dequeues expired timers from the TimerQueue.
 - Sets corresponding processes ready to run.

Timers and the Timer Queue

Timers

```
t.timeout(100);
```

Becomes

```
t.start(100);  
setNotReady();  
yield(1);  
label(1);
```

`t.start(100)` will insert a new timer object into the TimerQueue.

Barriers

```
sync(b);
```

Becomes

```
b.sync(this);  
yield(1);  
label(1);
```

`b.sync(this)` will

- * decrement the barrier's process counter
- * enqueue the process in the barrier's process list
- * set itself not ready

When counter reaches 0 all processes are set ready.

Alts

➤ We probably do not have time for this... but they are cool.

Results

- Timing
- Context switching
- Max process count
- Overhead (we will skip this one too)

Timings and Context Switches

Max Process Count

Conclusion

- ProcessJ code generator that produces Java source.
- JVMCSP runtime implemented.
- ASM bytecode instrumentation.
- Performs better than CPA'14 and JCSP.
- Can handle approximately **half a billion** processes in 128GB.

Future Work

- Multi-core Scheduler
- Network distribution
- Libraries
- Mobile processes
- Alts & claims are `busy waits' (remain ready to run and cycle through the run queue)
- More back ends

Other Back Ends

➔ Omar and Austin won gold in the UNLV College of Engineering Senior Design Competition for a CCSP code generator for ProcessJ
